

Consider the following UML representation of the Payment project and the inheritance relation.

Class Payment

The attribute `Current` of the class `Payment` can have only the value: LBP, Euro, USD.

Build the `Payment` Class. The constructor should receive 2 parameters. The `toString` function should print the amount, the currency and the equivalence in LBP as in the following example.

Amount value: 100

Currency: USD

Equivalent LBP : 150000

The function `Convert` gives the equivalence in LBP of the amount. One USD is equal to 1500 LBP. One Euro is equal to 1.5 USD.

Class CreditCardPayment

Build the CreditCardPayment Class. The constructor should receive 3 parameters.

The authorize() function returns true if the amount is less than 1000000 LBP, and false otherwise.

The toString function should print (the card number, the amount, the currency and the equivalence in LBP) in case of authorize function returns true, as in the following example:

Card number = 1123

Amount value: 100

Currency: USD

Equivalent LBP : 150000

The toString function prints "Operation failed" if the authorize function returns false.

Driver

Write a driver for the class Credit Card Payment that declares an array (PAY) of 4 Credit Card payments and sort them in ascending order according to the Amount value (use a function to sort the array).
